

ABSTRACT OF THE DISCLOSURE

An LED package has a light emitting element, a first optical section that is disposed around the light emitting
5 element, and a second optical section that is disposed around
the first optical while being separated from the first optical
section. A gap is formed between the first and second optical
sections. The gap allows part of light emitted from the light
emitting element to be radiated from the first optical section
10 as nearly parallel light converged in the direction vertical
to the center axis of the light emitting element. The second
optical section includes a reflection surface to reflect the
nearly parallel light in the direction parallel to the center
axis of the light emitting element.
